

Fortify DD

Live vendor risk briefs,
with citations, in under a
minute.

One input. One answer. Receipts attached.

Fortify DD takes a company name and optional domain, searches live public sources, fetches evidence, checks regulatory signals, and returns a structured vendor-risk brief that a reviewer can actually defend.

- Five scored risk dimensions
- Source URLs kept with every finding
- JSON output ready for product and alerts

Annual vendor reviews go stale almost immediately.

Risk changes between review cycles: litigation, sanctions, breach news, insolvency signals, hiring freezes, and adverse media all move faster than procurement workflows.

The work is slow

Teams still rely on questionnaires, web searches, and analyst notes that take too long to repeat at scale.

The evidence is scattered

Useful signals live across search results, registries, news, review sites, company pages, and filings.

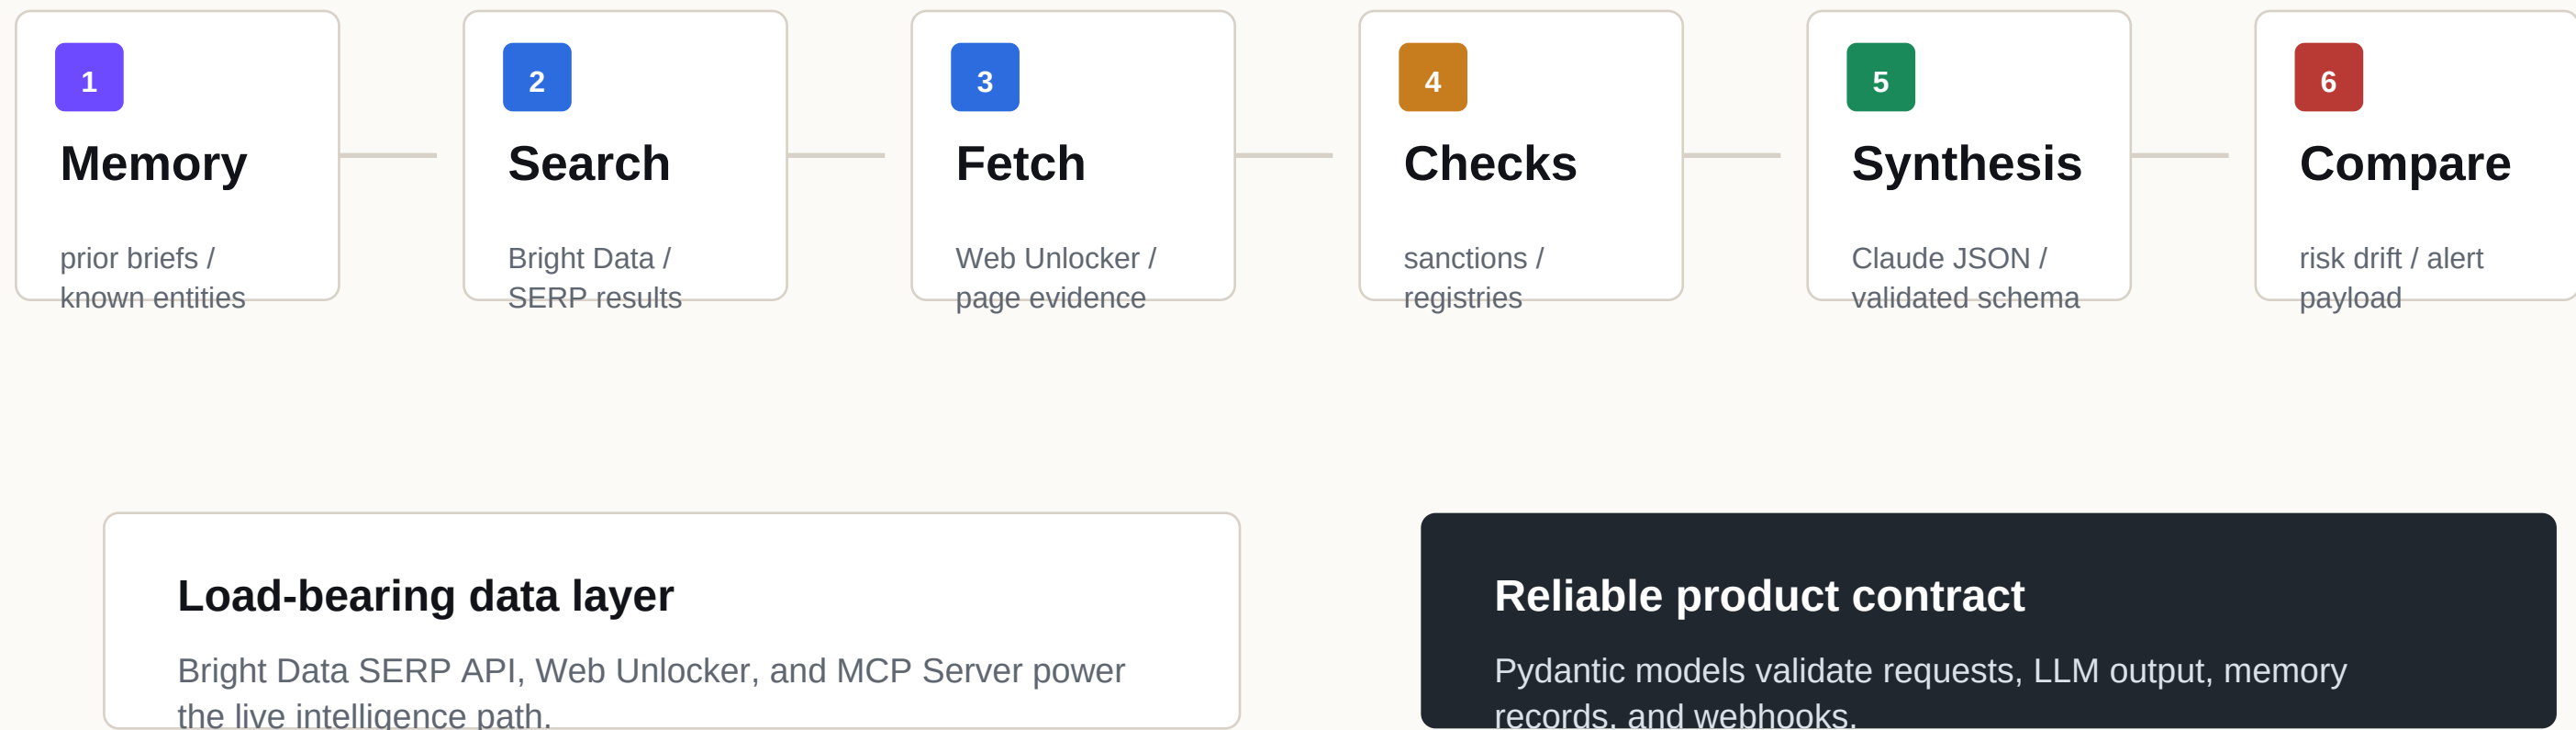

The output is hard to trust

A risk label without citations is not enough for compliance, procurement, or executive sign-off.

Fortify DD is built for the moment a reviewer asks: What changed, where is the proof, and what should we do now?

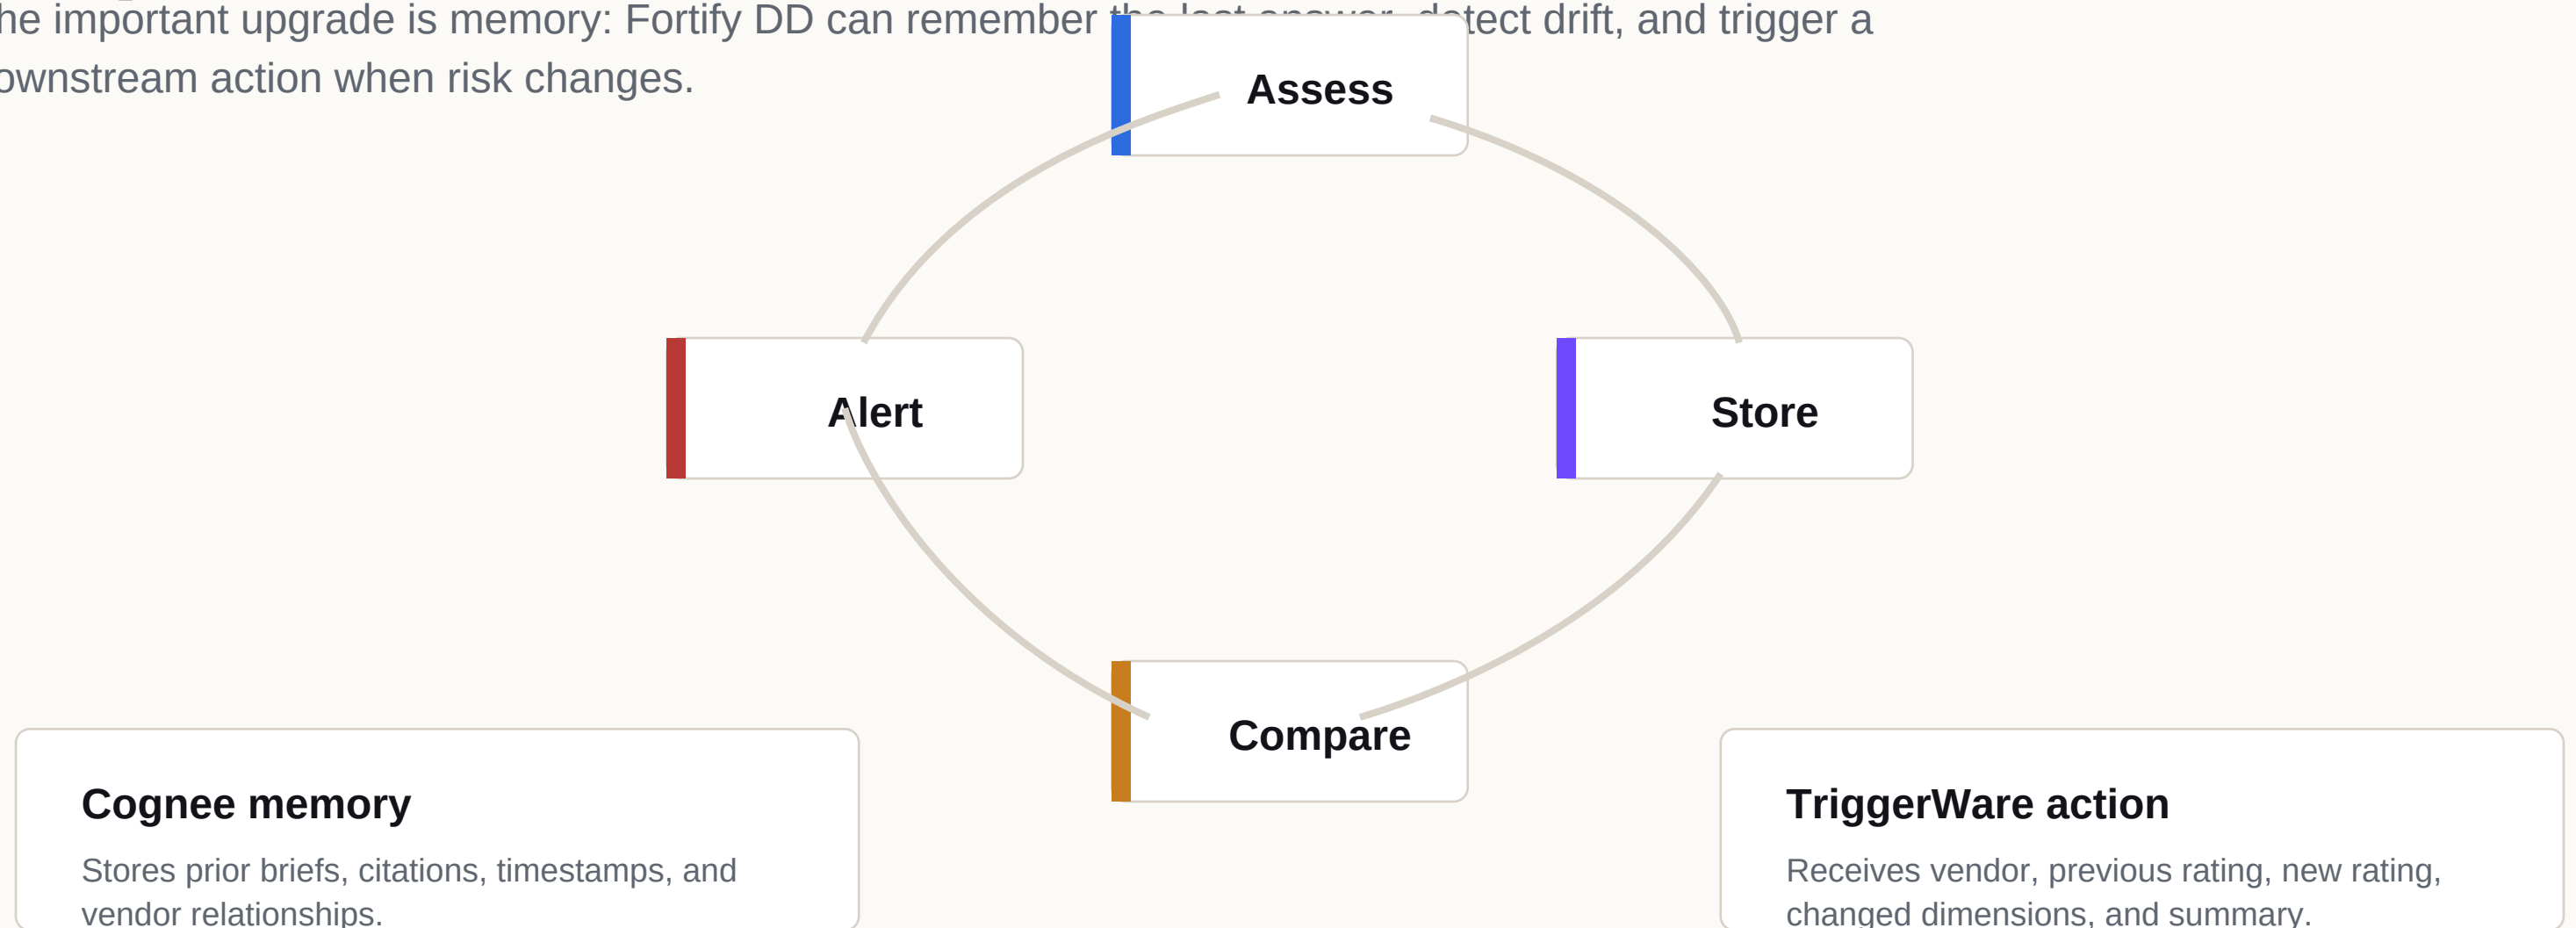

The agent keeps evidence intact from search to brief.

Each stage has a visible job in the demo, so the audience can follow how raw web signals become a cited risk decision.

Version 2.0 turns a brief into a monitoring loop.

The important upgrade is memory: Fortify DD can remember the last answer, detect drift, and trigger a downstream action when risk changes.

Prove the whole loop in three minutes.

Keep the demo narrow: one vendor assessment, one repeated run to show history, one simulated drift event that produces an alert payload.

00:00	Submit vendor	POST /assess with company name and optional domain.
00:45	Show progress	Memory, SERP, fetch, checks, synthesis, compare, store.
01:30	Read the brief	Overall R/A/G rating, five dimensions, cited evidence, recommended action.
02:15	Show history	GET /vendor/{name}/history returns prior assessment and drift.
02:45	Fire alert	POST /webhook/trigger returns dimensions_changed and summary.

Success criterion: a reviewer can see what changed, inspect the sources, and decide what to do next.
